AB The unprocessed polypeptide initially translated from the genome of a pos.-stranded RNA virus contains epitopic configurations that are not retained in the processed proteins. The structural protein region, in particular, loses an epitopic configuration upon processing at the cleavage site between the genomic region encoding the **core** protein and the genomic region encoding the protein adjacent the **core** protein, such as the envelope protein in HCV. Disclosed are compns., methods and assays relating to the diagnosis and detection of the presence of the pos.-stranded RNA virus, or antibodies to the pos.-stranded RNA virus, in a sample; compns. and methods for the induction of immune responses in, and vaccination of, an animal; and combination of the unprocessed **core** region with a non-structural protein (such as an **NS5** or an unprocessed **NS3-NS4 fusion** from HCV). Mol. cloning of cDNAs encoding the **core**-like antigen-adjacent protein and the **NS5** nonstructural protein of **hepatitis C** virus was described. ELISA using these recombinant proteins for detecting **hepatitis C** virus was demonstrated.

AB The unprocessed **core** protein region initially translated from the genome of **hepatitis C** virus (HCV) contains epitopic configurations that are not retained in the processed proteins. In particular, the **core** protein loses an epitopic configuration upon processing at the cleavage site between the genomic region (e.g., gene) encoding the **core** protein and the genomic region encoding the adjacent envelope region. The unprocessed epitopic configuration of the **core** region provides an improved ability to detect the presence of HCV, or antibodies to HCV, in a sample, including an unpurified sample or a sample of very small volume (which can be particularly helpful when testing a sample from an infant or other person having very little blood (or other suitable material) available for testing). Combining the unprocessed **core** region with a nonstructural protein (such as an **NS5** or an **NS3-NS4 fusion**) results in a synergistic effect that greatly enhances the already improved sensitivity and specificity provided by the unprocessed **core** region. The unprocessed epitopic configuration of the **core** region also provides an improved ability to induce an immune response upon administration of the **core** region into an animal. Recombinant methods are described for the preparation of a cloned DNA mol. (EN-80-2) derived from the HCV **core** and envelope regions and for a clone (EN-80-1) encoding the **NS5** nonstructural protein.

AB Multiple copy epitope immunoassays are produced by: (1) identifying nucleotide sequences that encode a plurality of different epitopes; (2) placing the nucleotide sequences into an expression cassette wherein at least two copies of a sequence coding for the same epitope, preferably from different strains of a pathogen, are placed in the cassette; (3) transforming a suitable host with the cassette in order to express the sequences encoding the epitopes; (4) purifying the expressed epitopes; and (5) coating the epitopes on a surface of a substrate. The purified epitopes are encompassed by the general structural formula (A)x-(B)y-(C)z which represents a linear amino acid sequence, B is an amino acid sequence of an epitope or cluster of epitopes and each B contains at least five and not more than 1,000 amino acids, y is an integer of 2 or more, A and C are each independently an amino acid sequence of an epitope or cluster of epitopes not adjacent to B in nature and x and z are each independently an integer of 0 or more wherein at least one of x and z is 1 or more. The epitopes of the invention are more soluble than and are therefore more easily purified than conventional epitopes. Further, the presence of repeating epitope sequences (repeating at least B in the same linear amino acid sequence from different strains of a pathogen) increases the sensitivity and specificity of the assay. Repeated epitope sequences in a single linear antigen also decreases masking problems and makes it possible to include a greater number of epitopes on a unit area of substrate thereby improving sensitivity in the detection of antibodies. Claimed are epitopes of proteins of **hepatitis C** virus and human immunodeficiency virus.

AB The genome of **hepatitis C** virus (HCV) consists of  
 seven functional regions: the **core**, E1, E2/NS1, NS2, NS3  
 , NS4, and NS5 regions. The U.S. Food and Drug  
 Administration-licensed 2.0G immunoassay for the detection of anti-HCV  
 uses proteins from the **core**, NS3, and NS4  
 regions. The 3.0G ELISA includes the protein from the NS5  
 region. The necessity of detecting antibodies to viral envelope proteins  
 (E1 and E2) and to different genotype samples has been demonstrated  
 previously. In this study we have attempted to improve the sensitivity of  
 the anti-HCV assay by developing a single multiple-epitope **fusion**  
 antigen (MEFA; MEFA-6) which incorporates all of the major immunodominant  
 epitopes from the seven functional regions of the HCV genome. A nucleic  
 acid sequence consisting of proteins from the viral **core**, E1,  
 E2, NS3, NS4, and NS5 regions and different  
 subtype-specific regions of the NS4 region was constructed,  
 cloned, and expressed in yeast. The epitopes present on this antigen can  
 be detected by epitope-specific monoclonal and polyclonal antibodies. In  
 a competition assay, the MEFA-6 protein competed with 83 to 96% of  
 genotype-specific antibodies from HCV genotype-specific peptides. This  
 recombinant antigen was subsequently used to design an anti-HCV  
 chemiluminescent immunoassay. We designed our assay using a monoclonal  
 anti-human IgG antibody bound to the solid phase. Because MEFA-6 is fused  
 with human superoxide dismutase (h-SOD), we used an anti-human superoxide  
 dismutase, di-Me acridinium ester-labeled monoclonal antibody for  
 detection. Our results indicate that MEFA-6 exposes all of the major  
 immunogenic epitopes. Its excellent sensitivity and specificity for the  
 detection of clin. seroconversion are demonstrated by this assay.

AB Human **hepatitis C** virus (HCV) has been identified as the etiol. agent of non-A, non-B hepatitis (NANBH). HCV viruses display considerable genotypic and phenotypic heterogeneity. Thus, there is considerable need in the art for more sensitive reagents that facilitate the detection of HCV variants. The genome of **hepatitis C** virus (HCV) consists of seven functional regions: the **core**, E1, E2/NS1, NS2, **NS3**, **NS4**, and **NS5** regions. An attempt was made to improve the sensitivity of anti-HCV assays by developing multiple copy epitope **fusion** antigens (MEFAs) which incorporate the major immunodominant epitopes from the functional regions of the HCV genome. These MEFAs are encompassed by the following generic structural formula: (A)x-(B)y-(C)z. This formula represents a linear amino acid sequence comprising multiple copies of one HCV epitope (A) linked to multiple copies of another HCV epitope (B) which in turn is linked to multiple copies of yet another HCV epitope (C). Expression vectors carrying nucleic acid sequences comprising MEFA antigens carrying multiple copies of epitopes derived from the viral **core**, E1, E2, **NS3**, **NS4**, and **NS5** regions were prepared. The resultant MEFA antigens were expressed, purified, and employed in suitable immunoassays for the detection of HCV-specific antisera. These antigens provide excellent sensitivity and specificity for the detection of HCV.

AB The genome of hepatitis C virus (HCV) consists of seven  
 functional regions: the **core**, E1, E2/NS1, NS2, **NS3**,  
**NS4**, and **NS5** regions. The U.S. Food and Drug  
 Administration-licensed 2.0G immunoassay for the detection of anti-  
 HCV uses proteins from the **core**, **NS3**, and  
**NS4** regions. The 3.0G ELISA includes the protein from the  
**NS5** region. The necessity of detecting antibodies to viral  
 envelope proteins (E1 and E2) and to different genotype samples has been  
 demonstrated previously. In this study we have attempted to improve the  
 sensitivity of the anti-HCV assay by developing a single  
 multiple-epitope **fusion** antigen (MEFA; MEFA-6) which  
 incorporates all of the major immunodominant epitopes from the seven  
 functional regions of the HCV genome. A nucleic acid sequence  
 consisting of proteins from the viral **core**, E1, E2, **NS3**  
 , **NS4**, and **NS5** regions and different subtype-specific  
 regions of the **NS4** region was constructed, cloned, and expressed  
 in yeast. The epitopes present on this antigen can be detected by  
 epitope-specific monoclonal and polyclonal antibodies. In a competition  
 assay, the MEFA-6 protein competed with 83 to 96% of genotype-specific  
 antibodies from HCV genotype-specific peptides. This  
**recombinant antigen** was subsequently used to design an  
 anti-HCV chemiluminescent immunoassay. We designed our assay  
 using a monoclonal anti-human IgG antibody bound to the solid phase.  
 Because MEFA-6 is fused with human superoxide dismutase (h-SOD), we used  
 an anti-human superoxide dismutase, di-Me acridinium ester-labeled  
 monoclonal antibody for detection. Our results indicate that MEFA-6  
 exposes all of the major immunogenic epitopes. Its excellent sensitivity  
 and specificity for the detection of clin. seroconversion are demonstrated  
 by this assay.

AB Immunoassays for detecting antibodies to antigens of hepatitis C virus (HCV) in a fluid sample are disclosed which use **recombinant antigens**. The antigens are **fusion** products with CMP-KDO synthetase (CKS) and are produced in Escherichia coli. The cloning vector pJO200 was used to fuse DNA encoding the recombinant proteins to DNA for CKS. Plasmid pHCV-34, encoding CKS-HCV **core** antigen (amino acids 1-150) **fusion** product, was prepared and expressed in E. coli. A screening immunoassay using this recombinant CKS-**core fusion** product and **fusion** protein CKS-33-BCD (prepared from plasmid pHCV-31; containing amino acid sequences from HCV **NS3** and **NS4** proteins) was sufficiently sensitive to detect seroconversion during the acute phase of HCV infection in chimpanzees. No preinoculation specimens were reactive.

 AB The anti-viral T cell response is believed to play a central role in the pathogenesis of hepatitis C virus infection. Since chronic evolution occurs in >50% of **HCV** infections, the sequential anal. of the T cell response from the early clin. stages of disease may contribute to define the features of the T cell response associated with recovery or chronic viral persistence. For this purpose, 21 subjects with acute hepatitis C virus infection were sequentially followed for an average time of 44 wk. Twelve patients normalized transaminase values that remained normal throughout the follow-up period; all but two cleared hepatitis C virus-RNA from serum. The remaining nine patients showed persistent viremia and elevated transaminases. Anal. of the peripheral blood T cell proliferative response to **core**, **E1**, **E1**, **NS3**, **NS4**, and **NS5 recombinant antigens** and synthetic peptides showed that responses to all hepatitis C virus antigens, except **E1**, were significantly more vigorous and more frequently detectable in patients who normalized transaminase levels than in those who did not. By sequential evaluation of the T cell response, a difference between the two groups of patients was already detectable at the very early stages of acute infection and then maintained throughout the followup period. The results suggest that the vigor of the T cell response during the early stages of infection may be a critical determinant of disease resolution and control of infection.

AB Third-generation screening assays for **HCV** antibodies were recently developed, in which a mixture of **recombinant antigens** from 4 different regions of the viral protein (**core**, **NS3**, **NS4**, **NS5**) was used. We reported the anal. performance and clin. usefulness of a 3rd-generation counting immunoassay (RANREAM **HCV**) with PAMIA 30 (Toa Medical Electronics Inc., Kobe). In the present study, we investigated a modified assay of RANREAM **HCV** to detect region-specific antibody by using single antigen from 4 different regions, and studied response pattern of **HCV** antibodies and region-specific antibody in the patients with **HCV** infection. **HCV** antibodies of the seroconversion panel serum samples (Boston Biomedica, Inc., USA) measured by RANREAM **HCV** were greatly coincident with those obtained by Ortho RIBA 3.0. The region-specific assay of serial sera from the patient with acute hepatitis revealed that anti-**core** antibody was produced at the initial stage of infection. In 165 patients with chronic hepatitis, pattern of region-specific antibody was different from case to case, although anti-**NS3** and anti-**core** antibodies seemed to be predominant. The change of pattern was not observed for at least 1 yr. All 2 cases who achieved complete remission with interferon showed low serum titer of anti-**core** antibody, in contrast to partial or non remission patients in which the level of anti-**core** antibodies was low in 6 of 16 cases.
